FEATURES:
- Manufactured using Linear Technology Space Qualified RH3845 Dice
- Radiation Hardened to 300 Krad(Si) (Method 1019.7 Condition A)
- High Voltage Operation: Up to 60V Input, and 36V Output
- Programmable Frequency 100-500KHz, or Synchronizable to 600KHz
- 65µA Shutdown Supply Current
- Antislope Compensation – Current Limit Unaffected by Duty Cycle
- Reverse Inductor Current Inhibit – Improves Efficiency with Light Loads
- External Compensation
- Contact MSK for MIL-PRF-38534 Qualification Status

DESCRIPTION:
The MSK5063RH is a radiation hardened wide input voltage range step-down synchronous switching regulator. The wide input range, programmable output voltage and switching frequency, make these regulators suitable for a wide variety of medium to high power applications. The adjustable operating frequency provides the flexibility to keep the switching noise out of sensitive frequency bands, and when synchronized, can be ganged out of phase with other regulators for reduced noise and component size. The MSK5063RH is hermetically sealed in a 46 pin flatpack, and is available with straight or gull wing leads.

EQUIVALENT SCHEMATIC

TYPICAL APPLICATIONS
- POL Applications
- Intermediate Bus Converter
- Satellite System Power Supply
- Step Down Synchronous Regulator
- High Efficiency Subsystem Supply

</table>
NOTES:

1. Unless otherwise specified VIN = 20V, BIAS = 10V, \( \overline{\text{SHDN}} \geq 2V \), \( R_{\text{SET}} = 49.9K\Omega \), SENSE- = SENSE+ = 10V, SGND = PGND = SYNC = 0V.

2. Guaranteed by design but not tested. Typical parameters are representative of device performance but are for reference only.

3. Industrial grade devices shall be tested to subgroup 1 unless otherwise specified.

4. Military grade devices (‘H’ and ‘K’ suffix) shall be 100% tested to subgroups 1, 2, 3, 4 and 7.

5. Subgroup 3, 6 and 8 available upon request.

6. Subgroup 1, 4, 7 \( \text{TC} = +25^\circ C \)
   Subgroup 2, 5, 8a \( \text{TC} = +125^\circ C \)
   Subgroup 3, 6, 8b \( \text{TC} = -55^\circ C \)

7. The -2V absolute maximum on the SWOUT pin is a transient condition. It is guaranteed by design, but not tested. Negative transients of up to -2V occur at SWOUT as part of normal operation. Direct application of power to the SWOUT pin may damage the device.

8. Continuous operation at or above absolute maximum ratings may adversely affect the device performance and/or life cycle.

9. Pre and post irradiation limits at 25°C, up to 300 Krad(Si) TID, are identical unless otherwise specified.
**PIN FUNCTIONS**

**VIN** – The VIN pins are the input supply pins for the control circuitry inside the device. Decouple to SGND with a low ESR capacitor located close to the pin.

**BIAS** – The BIAS pins provide access to the internal 8V bias supply for decoupling and optional external sourcing. It is the power supply for most of the internal functions and the MOSFET gate drive. BIAS can only source current and may be tied to an external source to improve efficiency and allow for lower voltage operation. If BIAS is tied to an external source greater than 6.5V the device will operate with Vin as low as 4V. This configuration reduces power dissipation in the device by bypassing the internal regulator. The BIAS pin charges the bootstrapped capacitor through a diode connected to the BOOST pin. In shutdown mode the BIAS pin sinks 20µA until the pin voltage is discharged to zero volts.

**NOTE:** When driving VBIAS from an external source, the source must be greater than or equal to 9V and connect through a series diode.

**PVIN** – The PVIN pins are the power input supply for the regulator. High frequency current switching is present at this node. Decouple to PGND with a low ESR tantalum capacitors in parallel with ceramic capacitors located close to the pins.

**PGND** – The PGND pins are the high-current ground reference. Connect them directly to the negative side of the PVIN decoupling capacitors. Care should be taken to make sure that these currents are not referenced by the SGND pin to avoid injecting noise into the ground reference.

**SGND** – the SGND pins should be connected to the negative side of the VIN capacitor. Use a common ground plane to minimize impedance, but locate the high current fast switching devices together so their returns remain local and do not corrupt the SGND reference.

**SHDN** – The SHDN pin provides a method to disable the device. This pin has 125mV of hysteresis. Pull below 1.23V (nominal) to disable switching, pull above 1.35V to enable switching. Pull below one VBE (0.7V nominal) to enter low power shutdown. A resistor divider to VIN can be used to set UVLO using the 1.35V threshold. When not in use, pull the pin up to VIN with a large value resistor. When exceeding the absolute maximum rating of 5V the pin voltage will be clamped at 6V nominal. Limit the current into the pin to less than 1mA to prevent overstress.

**SS** – The SS pin is used for soft start. It allows the user to program the rate of change of the output at start-up. The capacitance required for a given output slew rate can be calculated using the

\[
SS = 11\mu A(T_{SS}/1.231V)
\]

The pin should be left open if not in use.

**SWOUT** – The SWOUT pins are the switched output of the regulator. Connect these pins directly to the inductor of the output filter and optionally to the cathode of the schottky catch diode. The external schottky catch diode is optional.

**COMP** – The COMP pin provides a means to externally compensate the loop response of the controller. COMP is the output of the transconductance error amplifier. A capacitor to ground creates a pole in the control loop. A series RC creates a pole zero combination in the control loop. If the COMP pin is externally manipulated, use a series impedance of 1KΩ.

**MODE** – The MODE pin is used to inhibit or enable reverse current in the synchronous rectifier. Connect to VFB to inhibit reverse current. This allows discontinuous current (DCM) at light loads. The PWM will skip pulses to maintain regulation. This improves efficiency at very light load. Connect MODE to VCC to enable reverse current. This allows for continuous current (CCM) at light loads. This configuration is less efficient at light loads but operates at a constant switching frequency.

**SENSE** – The SENSE pin is the negative input to the current sense amplifier. The sensed inductor current limit is set to 100mV across the SENSE inputs.

\[
R_{SENSE} = 70mV/I_{OUT(MAX)}
\]

Given:

\[
I_{P-P} < 0.30 \times I_{OUT(MAX)}
\]

**SENSE+** – The SENSE+ pin is the positive input to the current sense amplifier. The sensed inductor current limit is set to 100mV across the SENSE inputs.

\[
R_{SENSE} = 70mV/I_{OUT(MAX)}
\]

Given:

\[
I_{P-P} < 0.30 \times I_{OUT(MAX)}
\]

**VFB** – The VFB (Feedback) pin is used to set the output voltage. Use a resistive divider to set the voltage at the VFB pin to 1.231V when the output is at the desired level.

\[
V_O = VFB \left(1 + \frac{R_1}{R_2}\right)
\]

**FSET** – The FSET pin programs the oscillator frequency via a single resistor to ground. The RSET resistor must be present even when synchronization mode is used—Use the formula or the table below to select the resistance value for a desired frequency.
The RMS current capability is related to power dissipation capability of the capacitor. Replace the capacitor with one that has a higher rating, or place more capacitors in parallel if more capability is needed. Sharing of ripple current between capacitors will be approximately equal if all of the capacitors are the same type, and preferably from the same lot. The RMS current seen by the input capacitors can be approximated by the following equation:

\[ I_{\text{RMS}} \approx I_{\text{OUT}} \times \sqrt{(3D^2 - 3D + 1)} \]

Given: \( D \approx V_{\text{OUT}} / V_{\text{IN}} \)

Parallel ceramic capacitors are required to filter the high frequency components of the switching waveform. Locate the bias supply capacitors close to the VIN and SGND pins on the MSK5063RH. Locate the power input capacitors close to the drain of the forward switch (PVIN) and the source of the synchronous rectifier (Power Ground). Use short, wide PCB lands to minimize parasitic impedances.

**SELECTING THE SWITCHING FREQUENCY**

The MSK5063RH can be set to operate over a frequency range of 100KHz to 500KHz, and is synchronizeable up to 600KHz. There are several factors to consider when selecting the operating frequency including: efficiency, component size, output ripple, application sensitive frequency bands, and the minimum on time of the controller. The output ripple voltage and efficiency will vary with frequency and input voltage. Higher frequencies increase switching losses, but use smaller inductors and/or bulk capacitors saving board space. Lower frequencies reduce switching losses, but increase ripple current and require larger inductors and/or bulk capacitance to achieve the same output ripple voltage.

**SELECTING THE OUTPUT CAPACITOR**

The output capacitor filters the ripple current from the inductor to an acceptable ripple voltage seen by the load. The primary factor in determining voltage ripple is the ESR of the output capacitor. The voltage ripple can be approximated as follows:

\[ V_{\text{P-P}} \approx I_{\text{P-P}} \times \text{ESR} \]

The capacitive term of the output voltage ripple lags the ESR term by 90° and can be calculated as follows:

\[ V_{\text{P-P(CAP)}} = I_{\text{P-P}} / (8 \times f \times c) \]

Where:
- \( C = \text{output capacitance in Farads} \)

Select a capacitor or combination of capacitors that can tolerate the worst-case ripple current with sufficient de-rating. When using multiple capacitors in parallel to achieve lower ESR or more bulk capacitance, sharing of ripple current between capacitors will be approximately equal if all of the capacitors are the same type, and preferably from the same lot. Low ESR tantalum capacitors are recommended over aluminum electrolytic capacitors. Use ceramic decoupling capacitors to minimize high frequency noise.
COMPENSATING THE LOOP

The feedback loop response can be optimized for the application by adjusting the values of the RC network from the COMP pin to ground. Analysis is recommended to determine the phase margin and gain margin at the specific input voltage and load conditions of the application. Typically, a single RC network from COMP to ground works well. An additional ceramic capacitor from COMP to ground may be needed to cancel the zero and prevent high frequency ringing or instability.

SELECTING THE INDUCTOR

The important parameters for inductor selection are: its value, volt-second product, saturation and RMS current. To determine the peak current in the inductor add ½ of the p-p ripple current to the desired IOUT(MAX). A typical starting point for peak to peak current ripple is 20% of IOUT(MAX). Use the following equation to determine the RMS current:

\[ I_{\text{RMS}} = I_{\text{DC}} \times \sqrt{1 + (1/3) \times (\Delta I/I_{\text{DC}})^2} \]

Given:
- \( I_{\text{DC}} \) = The DC output current
- \( \Delta I \) = ½ of the peak to peak ripple current

The minimum inductance value can be calculated as follows:

\[ L_{\text{MIN}} > \frac{V_{\text{OUT}} \times 2D_{\text{MAX}}-1}{D_{\text{MAX}}} \times \frac{R_{\text{SENSE}} \times 8.33}{f_{\text{SW}}} \]

Given:
- \( D_{\text{C}} \) = Duty Cycle = \( V_{\text{OUT}} / V_{\text{IN}} \)
- \( f_{\text{SW}} \) = Switching Frequency

This calculation also accommodates the max ripple/DC requirements for the slope compensation circuit.

The volt-seconds product can be calculated as follows:

\[ V^*S = V_i \times dt \]

Given:
- \( V_i \) = the inductor voltage (\( V_{\text{IN}} - V_{\text{O}} \))
- \( dt = V_{\text{O}} / (V_{\text{IN}} \times f_{\text{SW}}) \)

Allow sufficient derating to prevent saturation and/or overstress when selecting the inductor.

TOTAL DOSE RADIATION TEST PERFORMANCE

Radiation performance curves for TID testing have been generated for all testing performed by MSK. These curves show performance trends throughout the TID process, and will be located in the MSK5063RH radiation test report. The complete test report will be available in the RAD HARD PRODUCTS section of the MSK website.

For additional applications information, please reference Linear Technology’s® LT3845 data sheet.
